reading:  
Programming Abstractions in C++, Chapter ??

# Recent News

1.25 Million people in the U.S. have Type 1 Diabetes

# Diabetes

Diabetes is fully treatable, but management is a process that involves closely monitoring blood glucose levels through an under-the-skin sensor, and a trial & error process for delivering insulin through a wearable pump.

The sensor and the pump do not communicate with each other.

# Diabetes

Mismanagement can lead to low insulin levels, which can produce nerve and organ damage, seizures, and even death.

# Diabetes

However,

the FDA has just approved a new device, called a "hybrid closed loop" device where the pump and monitor *do* communicate. "The device uses advanced algorithms that can learn what the patient's needs are and can deliver hormones at variable rates."\*

This is computer science!

\* <http://futurism.com/a-cyborg-society-the-fda-has-approved-the-first-artificial-pancreas/>

# Diabetes

But, it isn't all computer science, of course: this device is a technological marvel, and it would not have been possible without the work of scientists, mathematicians, electrical engineers, mechanical engineers, computer scientists, materials scientists, and doctors, among many others. To regulate, market, and distribute the device, businesspeople, lawyers, advertisers, etc., will all be involved.

Working together, humans can be *awesome*.

# Diabetes

Whatever you major in, you have the potential to influence the world for good. Of course, we do have to "learn to walk before we run," and there is a lot to learn in CS before you are developing "advanced algorithms."

# Back to Regular Programming: Today's Topics

- Logistics
- If you used a for loop like this on the exam and got points off, please submit a regrade:
  - **foreach (int x in collection) { ... }**
- Regrade requests due Friday
- Current assignment: Priority Queue
- We know you are working hard on the assignments. We have decided to give everyone an extra late day.
- Linked Lists: Deleting a linked list entirely (e.g., in a destructor or clear() function).
- Priority Queues
- Binary Heaps
  - A tree, but not a binary search tree
  - The Heap Property
  - Parents have higher priority than children

# Back to Linked Lists

- There was a question on Piazza about destroying a linked list -- this is a key point of understanding, so let's write a linked list clear() function (and call it from the destructor).
- The big idea:
  - Traverse the list and call delete on each Node
  - Don't try to use memory you've already deleted!

# Priority Queues

- Sometimes, we want to store data in a “prioritized way.”
- Examples in real life:
  - Emergency Room waiting rooms
  - Professor Office Hours (what if a professor walks in? What about the department chair?)
  - Getting on an airplane (First Class and families, then frequent flyers, then by row, etc.)

# Priority Queues

- A “priority queue” stores elements according to their priority, and not in a particular order.
- This is fundamentally different from other position-based data structures we have discussed.
- There is no external notion of “position.”

# Priority Queues

- A priority queue, P, has three fundamental operations:
- **enqueue (k, e)** : insert an element e with key k into P.
- **dequeue ()** : removes the element with the highest priority key from P.
- **peek ()** : return an element of P with the highest priority key (does not remove from queue).

# Priority Queues

- Priority queues also have less fundamental operations:
- **size()**: returns the number of elements in P.
- **isEmpty()**: Boolean test if P is empty.
- **clear()**: empties the queue.
- **peekPriority()**: Returns the priority of the highest priority element (why might we want this?)
- **changePriority(string value, int newPriority)**: Changes the priority of a value.

# Priority Queues

- Priority queues are simpler than sequences: no need to worry about position (or `insert(index, value)`, `add(value)` to append, `get(index)`, etc.).
- We only need one `enqueue()` and `dequeue()` function

# Priority Queues

<b>Operation</b>	<b>Output</b>	<b>Priority Queue</b>
<b>enqueue(5,A)</b>	-	{(5,A)}
<b>enqueue(9,C)</b>	-	{(5,A),(9,C)}
<b>enqueue(3,B)</b>	-	{(5,A),(9,C),(3,B)}
<b>enqueue(7,D)</b>	-	{(5,A),(9,C),(3,B),(7,D)}
<b>peek()</b>	<b>B</b>	{(5,A),(9,C),(3,B),(7,D)}
<b>peekPriority()</b>	<b>3</b>	{(5,A),(9,C),(3,B),(7,D)}
<b>dequeue()</b>	<b>B</b>	{(5,A),(9,C),(7,D)}
<b>size()</b>	<b>3</b>	{(5,A),(9,C),(7,D)}
<b>peek()</b>	<b>A</b>	{(5,A),(9,C),(7,D)}
<b>dequeue()</b>	<b>A</b>	{(9,C),(7,D)}
<b>dequeue()</b>	<b>D</b>	{(9,C)}
<b>dequeue()</b>	<b>C</b>	{}
<b>dequeue()</b>	<b>error!</b>	{}
<b>isEmpty()</b>	<b>TRUE</b>	{}

# Binary Heaps

- For HW 5, you will build a priority queue using an unsorted array, a linked list, and ... a "binary heap"
- A heap is a *tree-based* structure that satisfies the heap property:
  - Parents have a higher priority key than any of their children.

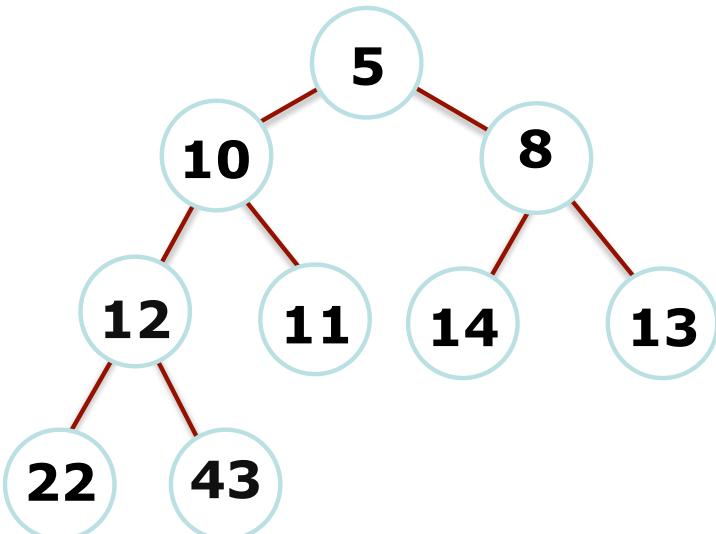

# Binary Heaps

- There are two types of heaps:

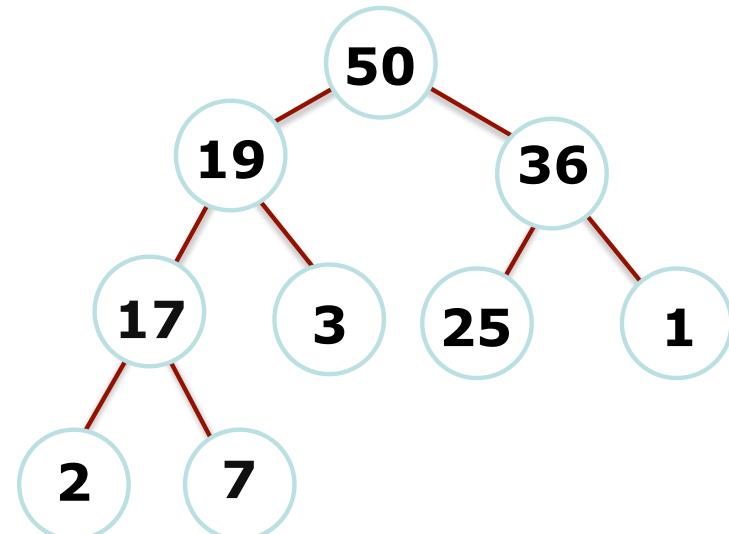

Min Heap

(root is the smallest element)

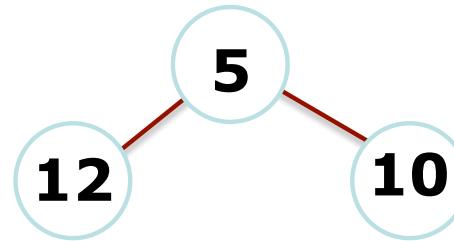

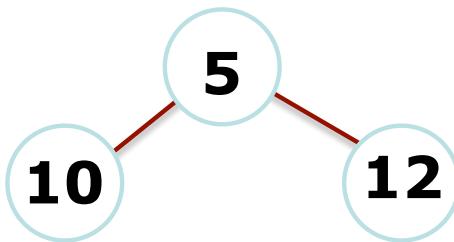

Max Heap

(root is the largest element)

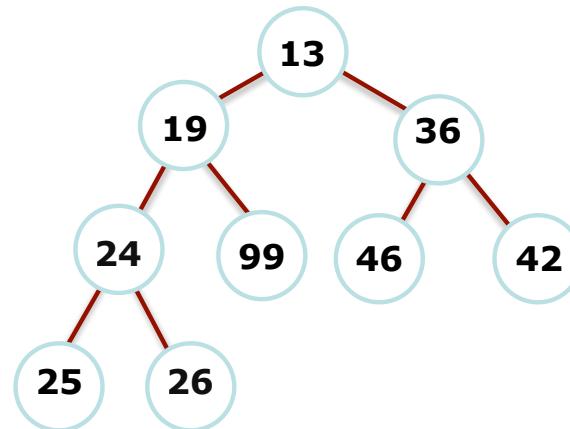

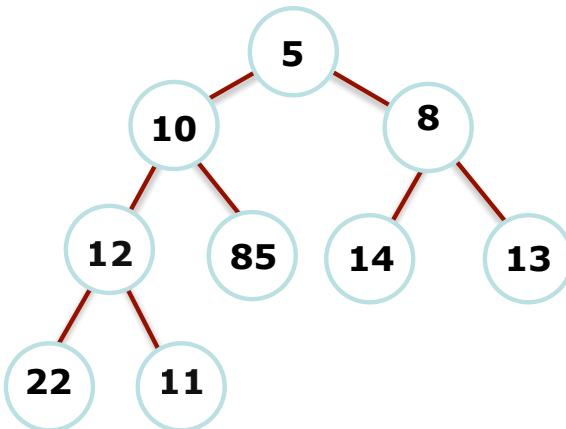

# Binary Heaps

- There are no implied orderings between siblings, so both of the trees below are min-heaps:

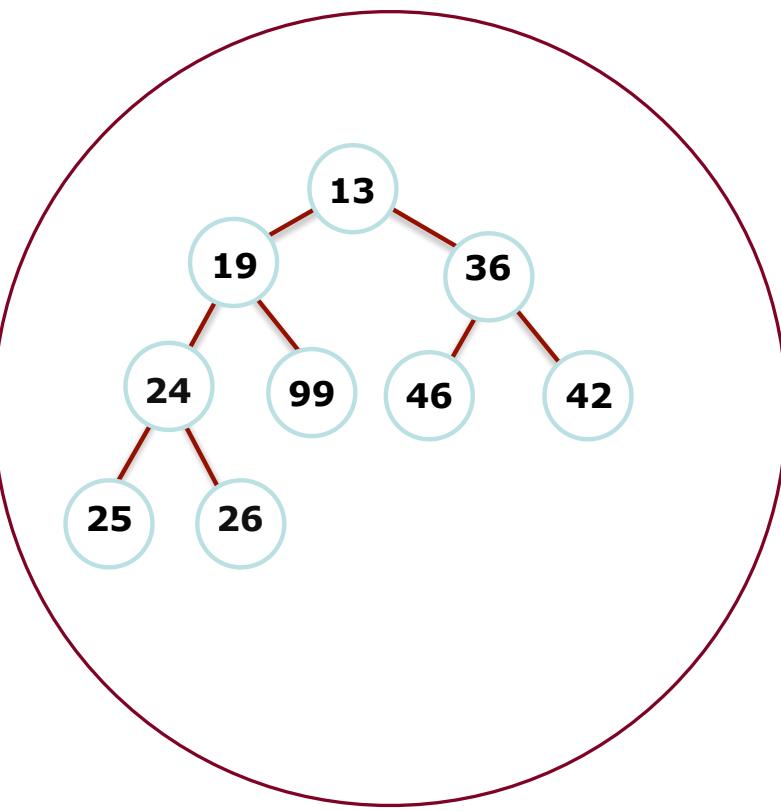

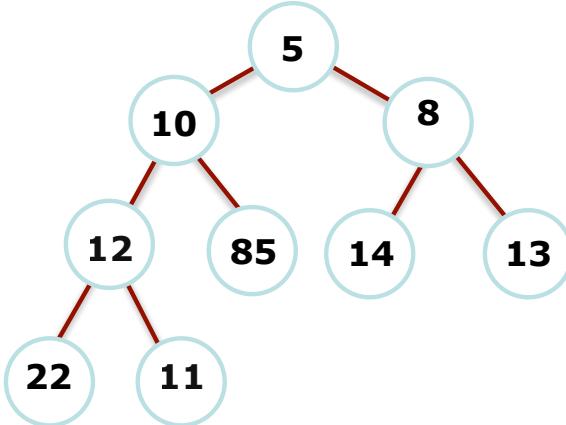

# Binary Heaps

- Circle the min-heap(s):

# Binary Heaps

- Circle the min-heap(s):

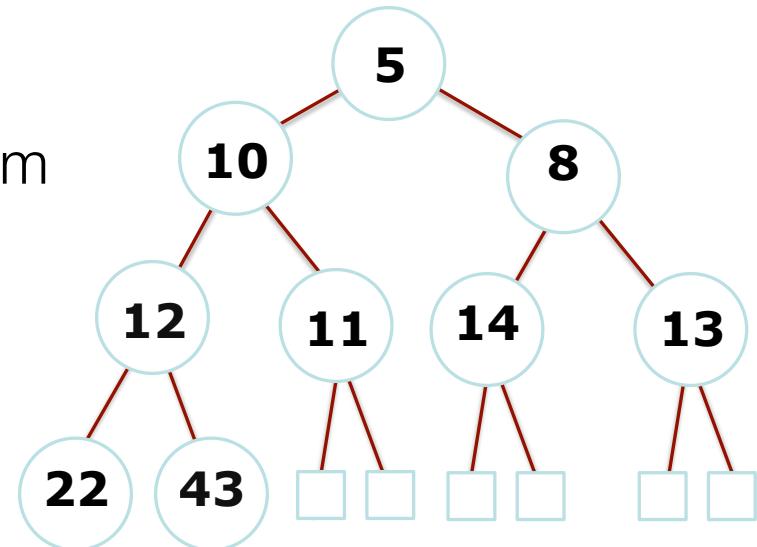

# Binary Heaps

Heaps are **completely filled**, with the exception of the bottom level. They are, therefore, "complete binary trees":

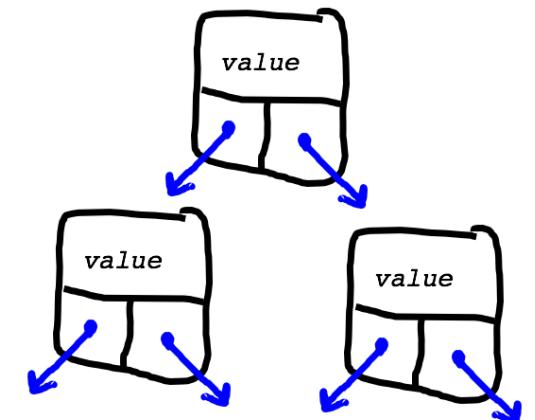

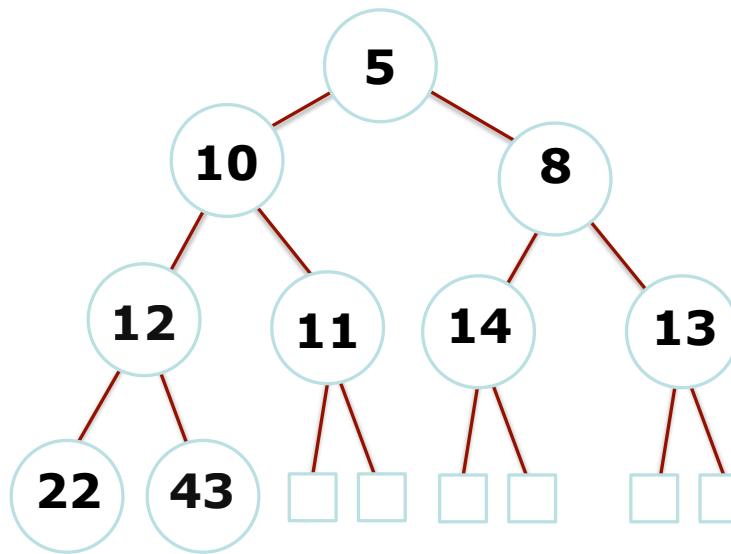

complete: all levels filled except the bottom  
binary: two children per node (parent)

- Maximum number of nodes
- Filled from left to right

# Binary Heaps

What is the best way to store a heap?

We could use a node-based solution, but...

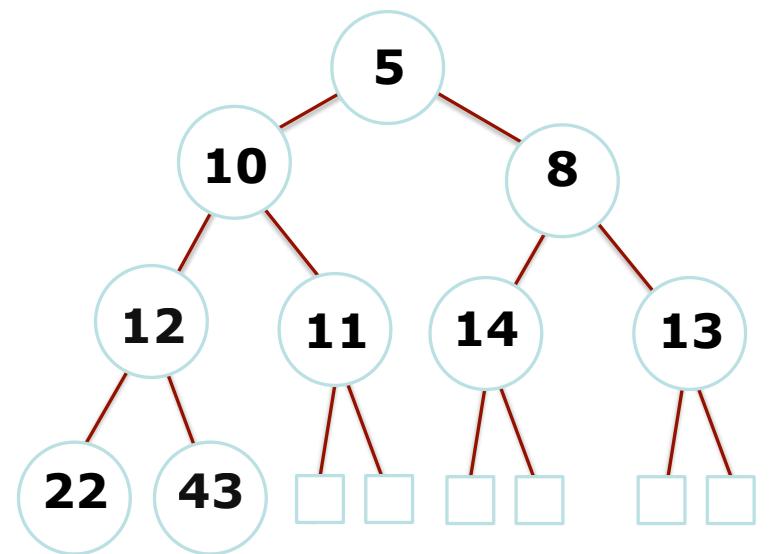

# Binary Heaps

It turns out that an array works **great** for storing a binary heap!

We will put the root at index 1 instead of index 0 (this makes the math work out just a bit nicer).

	5	10	8	12	11	14	13	22	43		
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

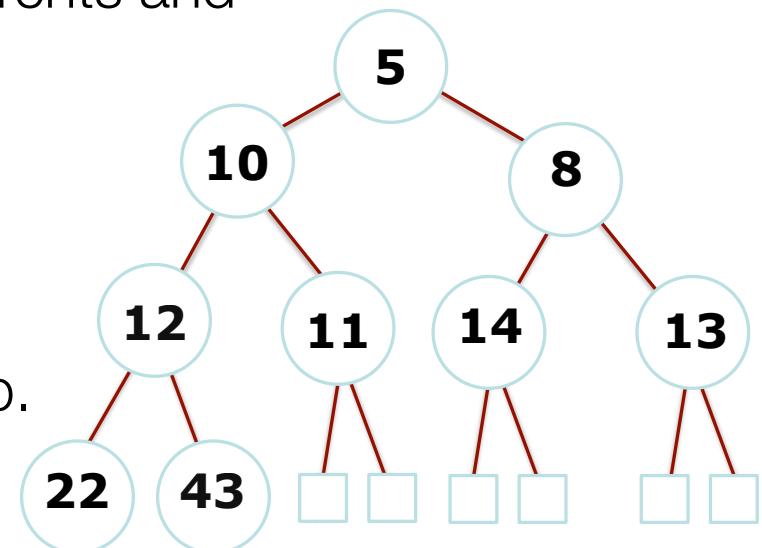

# Binary Heaps

The array representation makes determining parents and children a matter of simple arithmetic:

- For an element at position  $i$ :
  - left child is at  $2i$
  - right child is at  $2i+1$
  - parent is at  $\lfloor i/2 \rfloor$
- *heapSize*: the number of elements in the heap.

	<b>5</b>	<b>10</b>	<b>8</b>	<b>12</b>	<b>11</b>	<b>14</b>	<b>13</b>	<b>22</b>	<b>43</b>		
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

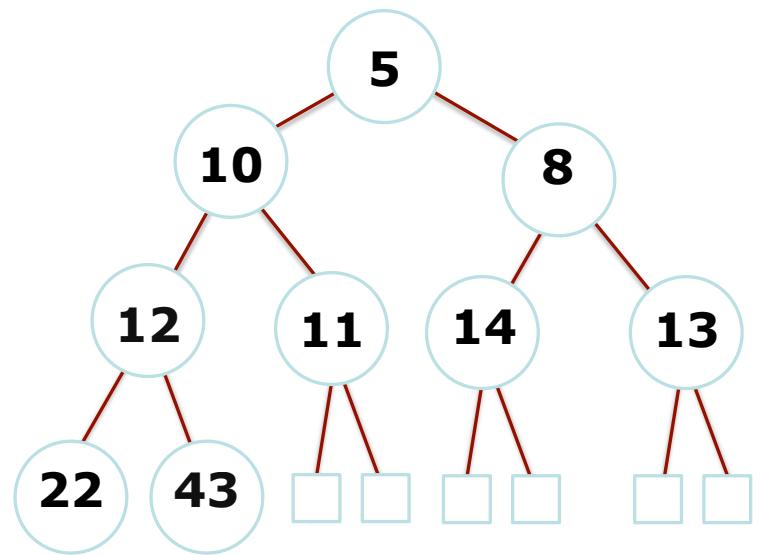

# Heap Operations

Remember that there are three important priority queue operations:

1. **peek ()**: return an element of h with the smallest key.
2. **enqueue (k , e)** : insert an element e with key k into the heap.
3. **dequeue ()** : removes the smallest element from h.

We can accomplish this with a heap!  
We will just look at keys for now -- just know that we will also store a value with the key.

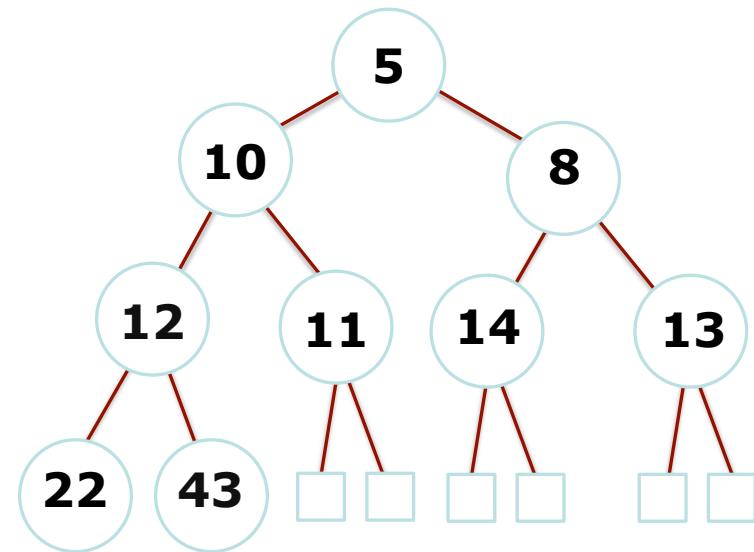

# Heap Operations: peek()

**peek () :**

Just return the root!  
**return heap[1]**

O(1) yay!

	<b>5</b>	<b>10</b>	<b>8</b>	<b>12</b>	<b>11</b>	<b>14</b>	<b>13</b>	<b>22</b>	<b>43</b>		
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

# Heap Operations: enqueue(k)

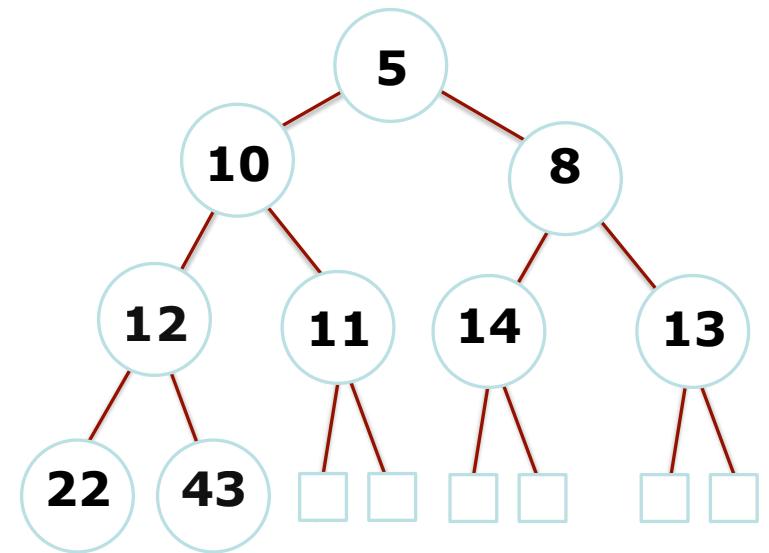

28

## enqueue (k)

- How might we go about inserting into a binary heap?

## enqueue (9)

	5	10	8	12	11	14	13	22	43		
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

# Heap Operations: enqueue(k)

## Heap Operations: **enqueue (k)**

1. Insert item at element **array [heap.size ()+1]**

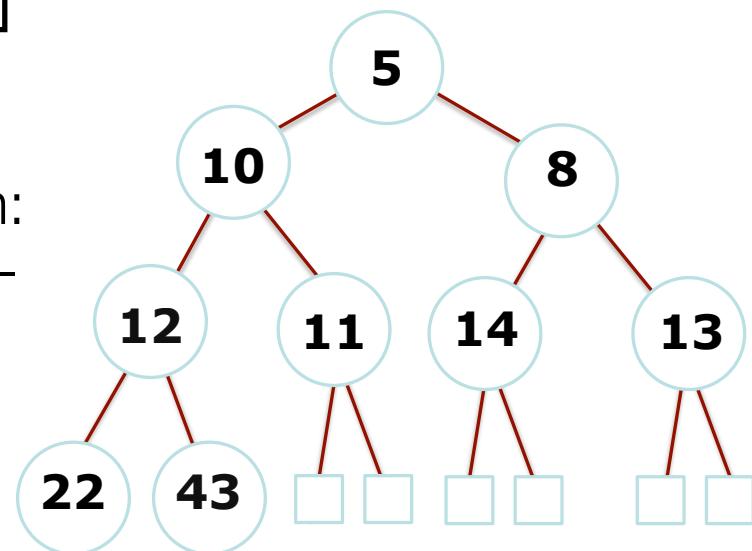

(this probably destroys the heap property)

2. Perform a “bubble up,” or “up-heap” operation:

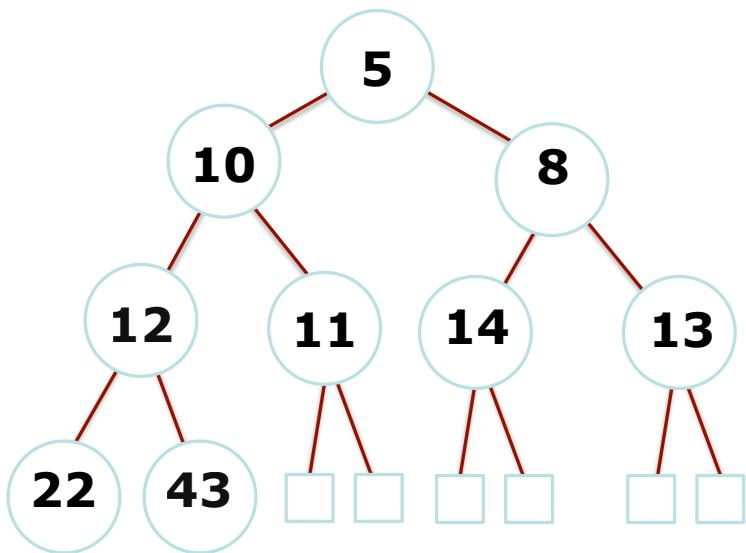

a. Compare the added element with its parent –  
if in correct order, stop

b. If not, swap and repeat step 2.

See animation at: <http://www.cs.usfca.edu/~galles/visualization/Heap.html>

# Heap Operations: enqueue(9)

	5	10	8	12	11	14	13	22	43		
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

Start by inserting the key at the first empty position.  
This is always at index **heap.size() + 1**.

# Heap Operations: enqueue(9)

	5	10	8	12	11	14	13	22	43	9	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

Start by inserting the key at the first empty position.  
This is always at index **heap.size() + 1**.

# Heap Operations: enqueue(9)

	5	10	8	12	11	14	13	22	43	9	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

Look at parent of index 10, and compare: do we meet the heap property requirement?

No -- we must swap.

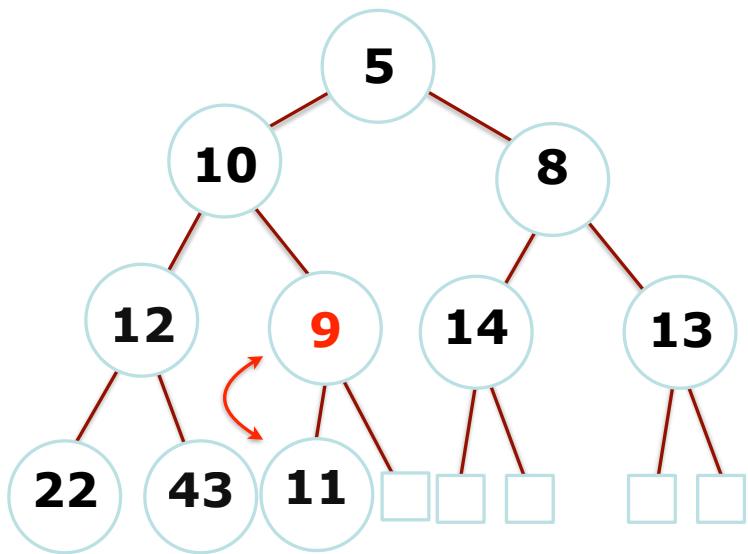

# Heap Operations: enqueue(9)

	5	10	8	12	11	14	13	22	43	9	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

# Heap Operations: enqueue(9)

	5	10	8	12	9	14	13	22	43	11	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

A red curved arrow points from the value 9 in the array to the corresponding node in the heap tree, indicating the insertion operation.

# Heap Operations: enqueue(9)

	5	10	8	12	9	14	13	22	43	11	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

Look at parent of index 5, and compare: do we meet the heap property requirement?

No -- we must swap. This "bubbling up" won't ever be a problem if the heap is "already a heap" (i.e., already meets heap property for all nodes)

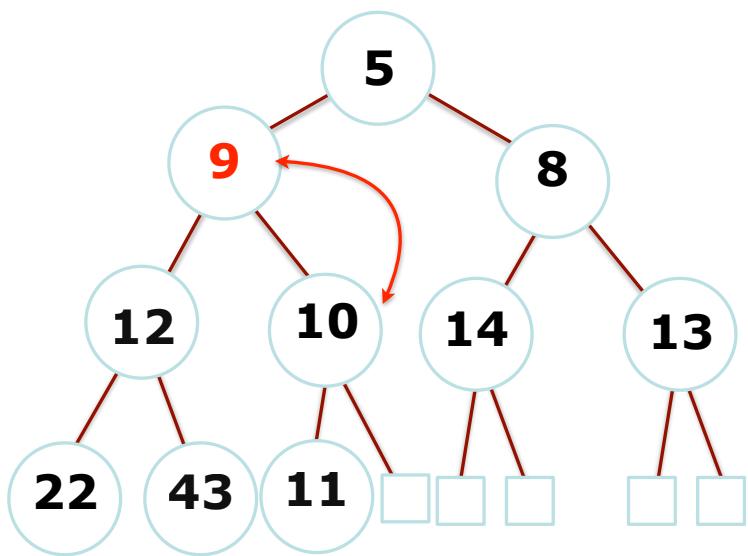

# Heap Operations: enqueue(9)

	5	10	8	12	9	14	13	22	43	11	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

# Heap Operations: enqueue(9)

	5	9	8	12	10	14	13	22	43	11	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

# Heap Operations: enqueue(9)

No swap necessary between index 2 and its parent.  
We're done bubbling up!

	<b>5</b>	<b>9</b>	<b>8</b>	<b>12</b>	<b>10</b>	<b>14</b>	<b>13</b>	<b>22</b>	<b>43</b>	<b>11</b>	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

Complexity?  $O(\log n)$  - yay!

Average complexity for random inserts:

$O(1)$ , see: [http://ieeexplore.ieee.org/xpls/abs\\_all.jsp?arnumber=6312854](http://ieeexplore.ieee.org/xpls/abs_all.jsp?arnumber=6312854)

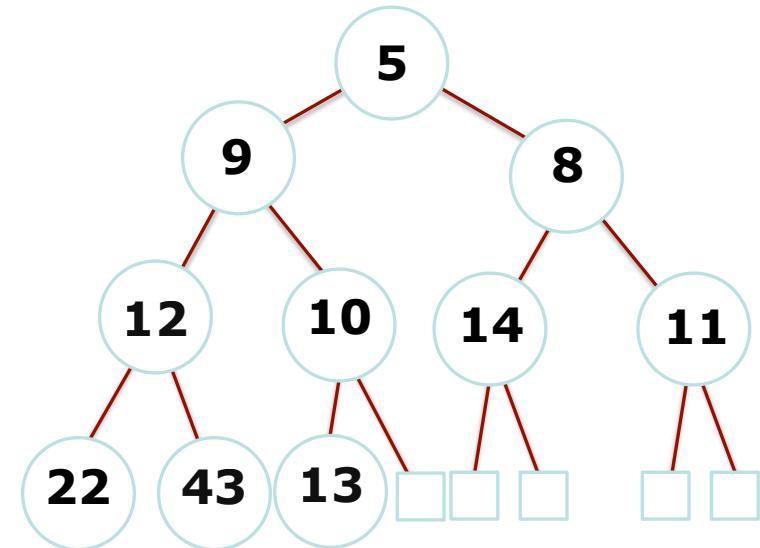

# Heap Operations: dequeue()

- How might we go about removing the minimum?

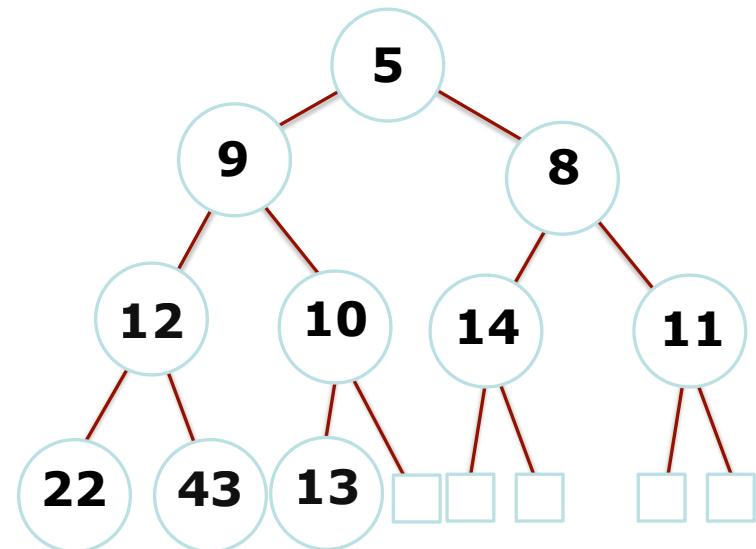

**dequeue ()**

	<b>5</b>	<b>9</b>	<b>8</b>	<b>12</b>	<b>10</b>	<b>14</b>	<b>11</b>	<b>22</b>	<b>43</b>	<b>13</b>	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

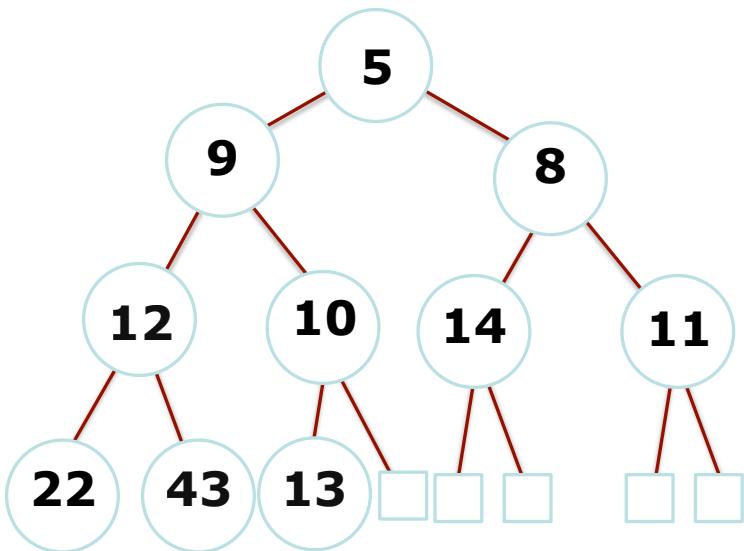

# Heap Operations: dequeue()

1. We are removing the root, and we need to retain a complete tree: replace root with last element.
2. **“bubble-down”** or “down-heap” the new root:
  - a. Compare the root with its children, if in correct order, stop.
  - b. If not, swap with smallest child, and repeat step 2.
  - c. Be careful to check whether the children exist (if right exists, left must...)

# Heap Operations: dequeue()

	<b>5</b>	<b>9</b>	<b>8</b>	<b>12</b>	<b>10</b>	<b>14</b>	<b>11</b>	<b>22</b>	<b>43</b>	<b>13</b>	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

# Heap Operations: dequeue()

Remove root (will return at the end)

	<b>5</b>	<b>9</b>	<b>8</b>	<b>12</b>	<b>10</b>	<b>14</b>	<b>11</b>	<b>22</b>	<b>43</b>	<b>13</b>	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

# Heap Operations: dequeue()

Move last element (at `heap[heap.size() - 1]`)  
to the root (this may be unintuitive!) to begin  
bubble-down

	<b>5</b>	<b>9</b>	<b>8</b>	<b>12</b>	<b>10</b>	<b>14</b>	<b>11</b>	<b>22</b>	<b>43</b>	<b>13</b>	
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

Don't forget to decrease heap size!

# Heap Operations: dequeue()

Compare children of root with root: swap root with the smaller one (why?)

	13	9	8	12	10	14	11	22	43		
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

# Heap Operations: dequeue()

Keep swapping new element if necessary. In this case: compare 13 to 11 and 14, and swap with smallest (11).

	8	9	13	12	10	14	11	22	43		
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

# Heap Operations: dequeue()

13 has now bubbled down until it has no more children, so we are done!

	<b>8</b>	<b>9</b>	<b>11</b>	<b>12</b>	<b>10</b>	<b>14</b>	<b>13</b>	<b>22</b>	<b>43</b>		
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

Complexity?  $O(\log n)$  - yay!

# Heaps in Real Life

- Heapsort (see extra slides)
- Google Maps -- finding the shortest path between places
- All priority queue situations
- Kernel process scheduling
- Event simulation
- Huffman coding

# Heap Operations: building a heap from scratch

What is the best method for building a heap from scratch (buildHeap())

14, 9, 13, 43, 10, 8, 11, 22, 12

We could insert each in turn.

An insertion takes  $O(\log n)$ , and we have to insert  $n$  elements

Big O?  $O(n \log n)$

# Heap Operations: building a heap from scratch

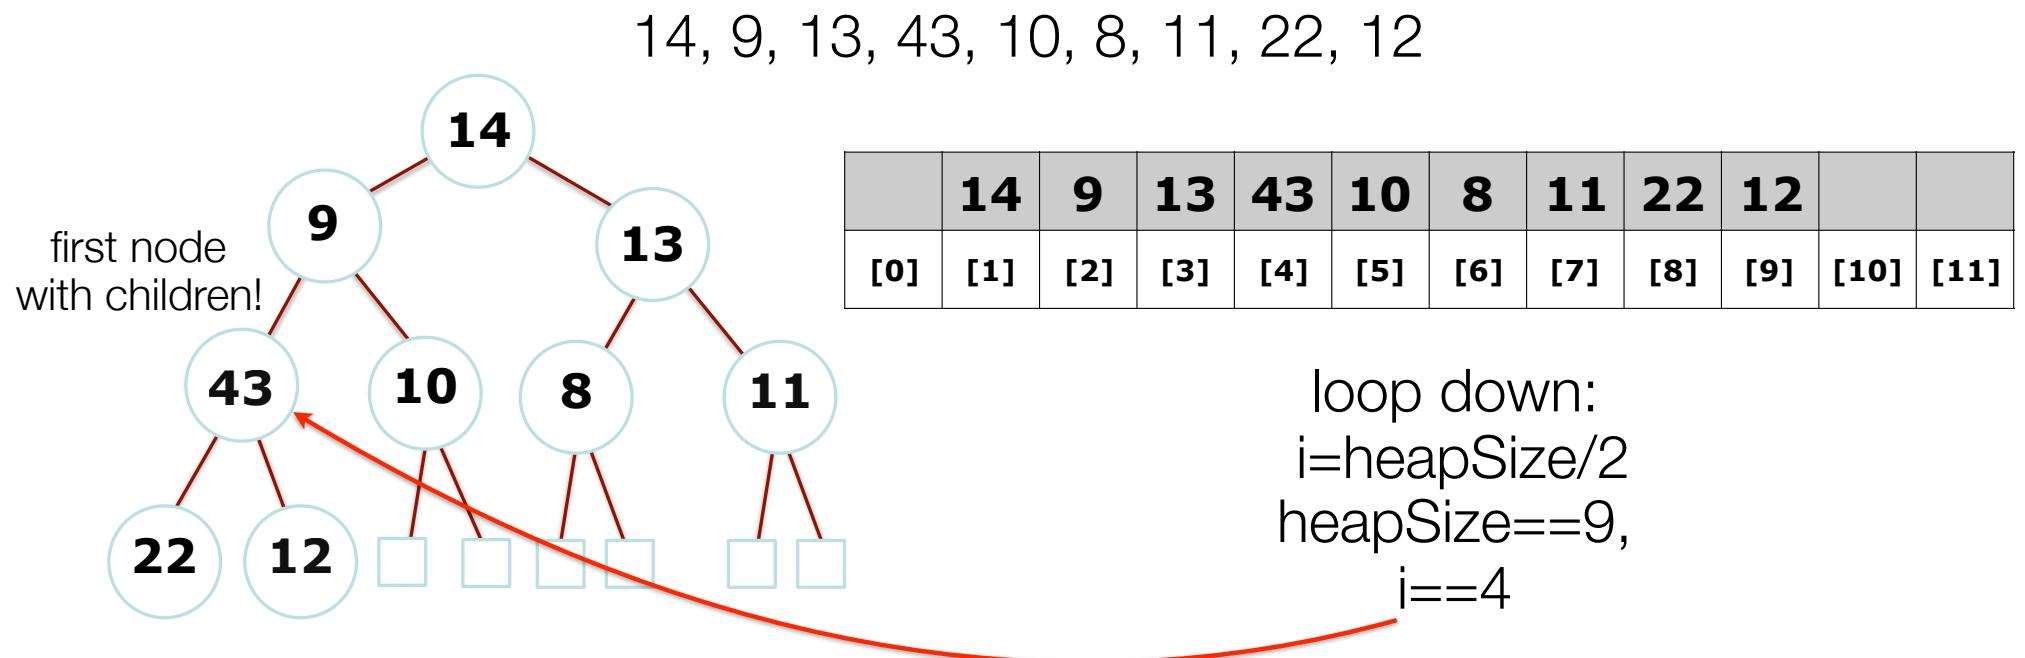

There is a better way: **heapify()**

1. Insert all elements into a binary tree in original order ( $O(n)$ )
2. Starting from the lowest completely filled level at the first node with children (e.g., at position  $n/2$ ), down-heap each element (also  $O(n)$ ) to heapify the whole tree).

```
for (int i=heapSize/2;i>0;i--) {  
    downHeap(i);  
}
```

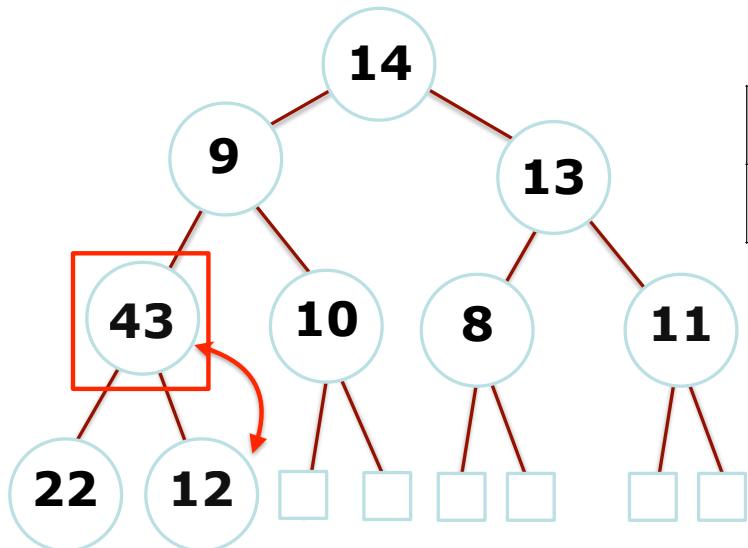

# Heap Operations: building a heap from scratch

# Heap Operations: building a heap from scratch

14, 9, 13, 43, 10, 8, 11, 22, 12

	<b>14</b>	<b>9</b>	<b>13</b>	<b>43</b>	<b>10</b>	<b>8</b>	<b>11</b>	<b>22</b>	<b>12</b>		
[0]	[1]	[2]	[3]	[4]	[5]	[6]	[7]	[8]	[9]	[10]	[11]

# Extra Slides

- We can perform a full heap sort in place, in  $O(n \log n)$  time.
- First, heapify an array (i.e., call build-heap on an unsorted array)
- Second, iterate over the array and perform dequeue(), but instead of returning the minimum elements, swap them with the last element (and also decrease heapSize)
- When the iteration is complete, the array will be sorted from low to high priority.

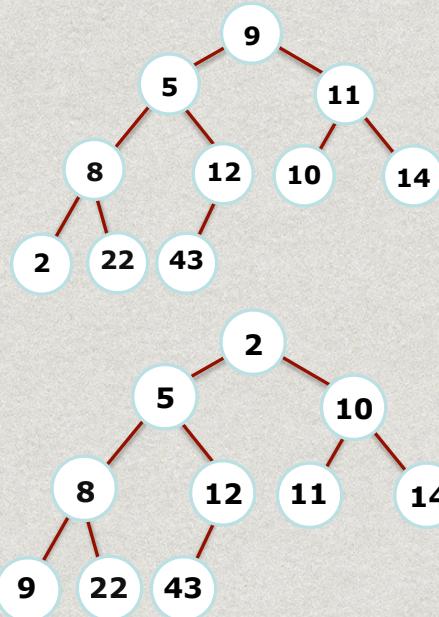

## Extras: HeapSort – Heapify first

Unheaped:

	<b>9</b>	<b>5</b>	<b>11</b>	<b>8</b>	<b>12</b>	<b>10</b>	<b>14</b>	<b>2</b>	<b>22</b>	<b>43</b>

Complexity:  $O(n \log n)$

## HeapSort Empirical Results (Java)

## HeapSort Empirical Results (C++)

## Extras: Why is buildheap() O(n)?

80

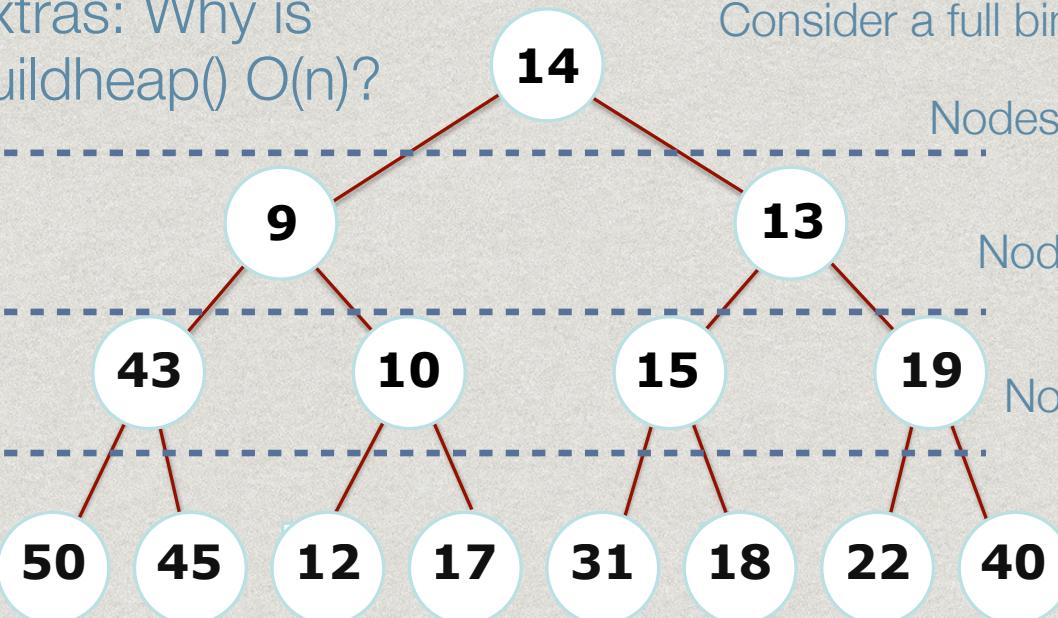

Consider a full binary heap data structure with n nodes.

Nodes at this level: 1, work done:  $c * (1) * \log n$

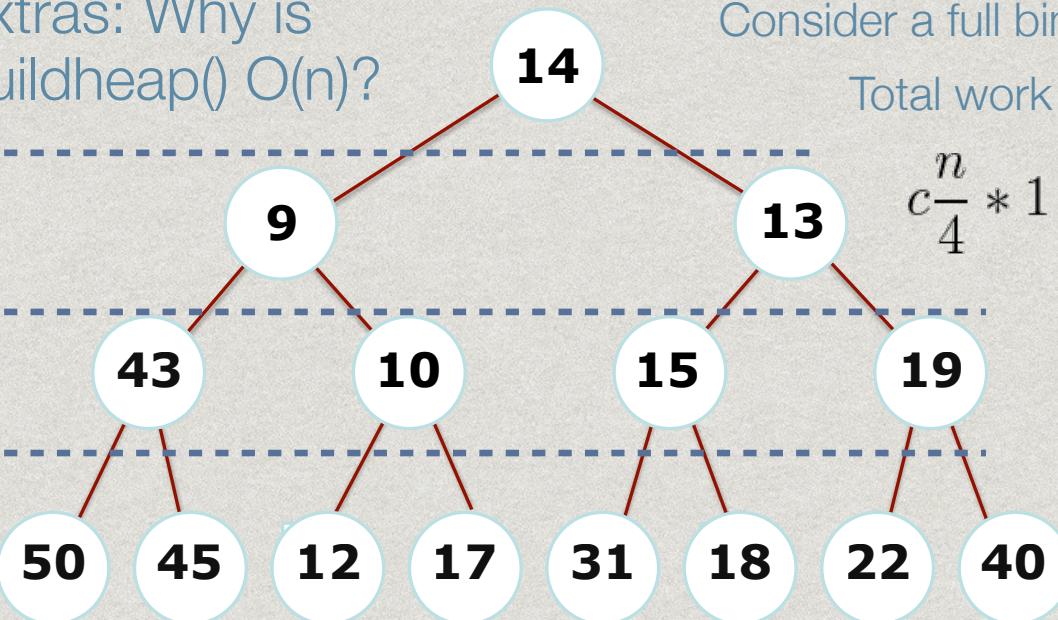

Nodes at this level:  $n/8$ , work done:  $c * n/8 * 2$

Nodes at this level:  $n/4$ , work done:  $c * n/4 * 1$   
(possible swaps to bottom level)

Work at this level: none

Extras: Why is  
buildheap() O(n)?

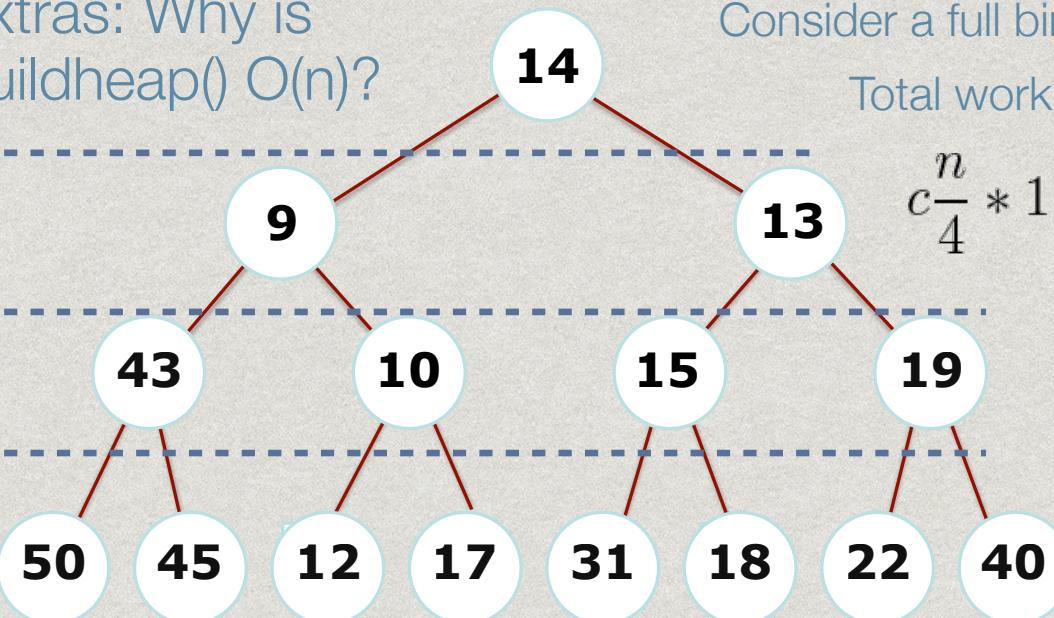

Consider a full binary heap data structure with n nodes.

Total work done:

$$c \frac{n}{4} * 1 + c \frac{n}{8} * 2 + c \frac{n}{16} * 3 + \dots + c(1) * \lg(n)$$

## Extras: Why is buildheap() O(n)?

Consider a full binary heap data structure with  $n$  nodes.

Total work done:

$$c \frac{n}{4} * 1 + c \frac{n}{8} * 2 + c \frac{n}{16} * 3 + \dots + c(1) * \lg(n)$$

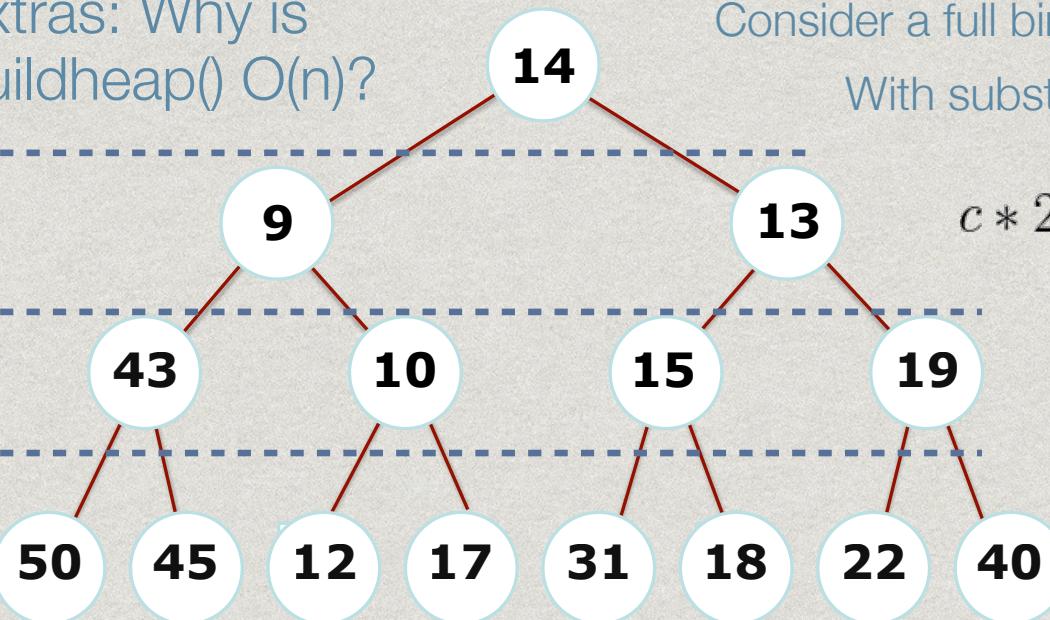

$$\text{Substitution: } \frac{n}{4} = 2^k$$

Must do some math for  $\lg(n)$ :

$$n = 4 * 2^k = 2^2 * 2^k = 2^{k+2}$$

$$\lg(n) = \lg(2^{k+2}) = k + 2$$

Extras: Why is  
buildheap() O(n)?

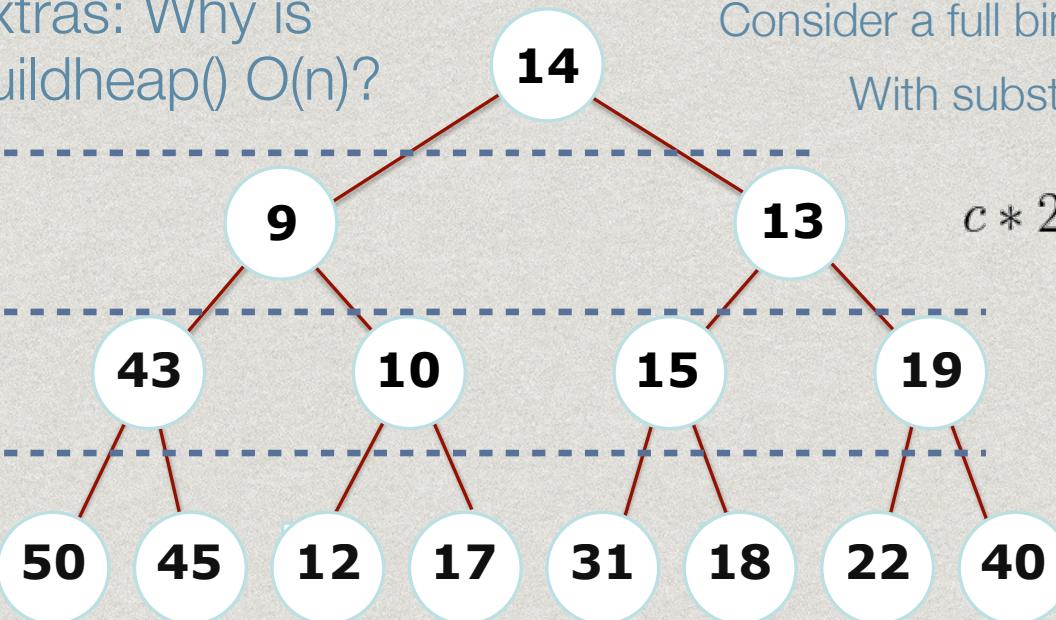

Consider a full binary heap data structure with n nodes.  
With substitution, and pulling out  $c * 2^k$ :

$$c * 2^k \left( \frac{1}{2^0} + \frac{2}{2^1} + \frac{3}{2^2} + \dots + \frac{k+2}{2^k} \right)$$

Simplify a bit more:

$$\frac{k+2}{2^k} = \frac{k+1+1}{2^k} = \frac{k+1}{2^k} + \frac{1}{2^k}$$

Extras: Why is  
buildheap() O(n)?

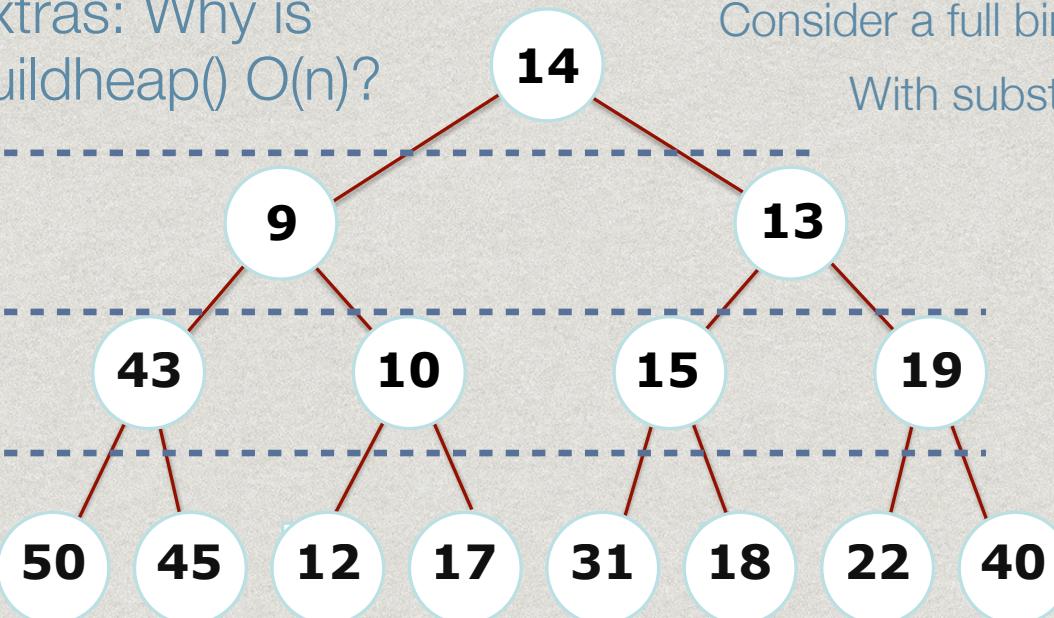

Consider a full binary heap data structure with n nodes.  
With substitution, and pulling out  $c * 2^k$ :

$$c * 2^k \left( \frac{1}{2^0} + \frac{2}{2^1} + \frac{3}{2^2} + \dots + \frac{k+2}{2^k} \right)$$

$$c * 2^k \left( \sum_{i=0}^k \frac{i+1}{2^i} + \frac{1}{2^k} \right)$$

$$\sum_{i=0}^k \frac{i+1}{2^i} = 4$$

Extras: Why is  
buildheap() O(n)?

Consider a full binary heap data structure with  $n$  nodes.  
With substitution, and pulling out  $c * 2^k$ :

$$c * 2^k \left( 4 + \frac{1}{2^k} \right)$$

$$4c * 2^k + c$$

Substitution:  $\frac{n}{4} = 2^k$

$c * n + c$  Linear amount of work!
